Working with Configuration Files

Inversion of Control and Dependency Injection

Class implementation has to change when a dependency changes

Difficult to test

Class manages the lifetime of the dependency

This is tight coupling

Inversion of Control

Inversion of Control delegates the function of selecting a concrete implementation type for a class's dependencies to an external component.

Dependency Injection

Dependency Injection is a specialization of the Inversion of Control pattern. The Dependency Injection pattern uses an object - the container - to initialize objects and provide the required dependencies to the object.

```
public class PointsOfInterestController :  
Controller  
{  
  
    private  
    ILogger<PointsOfInterestController>  
    _logger;  
  
    public PointsOfInterestController(  
        ILogger<PointsOfInterestController>  
        logger)  
    {  
        _logger = logger;  
    }  
  
    ...  
}
```

◀ **Interface, not concrete
implementation**

◀ **Constructor injection**

Inversion of Control and Dependency Injection

Dependency Injection is built into ASP.NET Core

ConfigureServices is used to register services with the built-in container

Demo

Injecting and using a logger

Demo

Logging to a file

Demo

Implementing and using a
custom service

Demo

Working with configuration files

Demo

Scoping configuration to environments

Summary

Dependency injection

- Specialization of IoC
- Loose coupling, less code changes, better testability

Summary

Custom services are registered in `ConfigureServices`

- Transient
- Scoped
- Singleton

Use configuration files for configuration data, scoped to a specific environment
